The EuroQol Group

- The EuroQol Group is a network of international multidisciplinary researchers devoted to the measurement of health status. Established in 1987, the EuroQol Group originally consisted of researchers from Europe, but nowadays includes members from North and South America, Asia, Africa, Australia, and New Zealand. The Group is responsible for the development of EQ-5D, a preference-based measure of health status that is now widely used in clinical trials, observational studies, and other health surveys. The EuroQol Group has been holding annual scientific meetings since its inception in 1987.
- The EuroQol Group can be justifiably proud of its collective scientific achievements over the last 20 years. Research areas include valuation, EQ-5D use in clinical studies and in population surveys, experimentation with the EQ-5D descriptive system, computerized applications, interpretation of EQ-5D ratings, and the role of EQ-5D in measuring social inequalities in self-reported health.
- The EuroQol Group's website (www.euroqol.org) contains detailed information about EQ-5D, guidance for users, a list of available language versions, EQ-5D references, and contact details.
- EQ-5D is a standardized measure of health status developed by the EuroQol Group in order to provide a simple, generic measure of health for clinical and economic appraisal. Applicable to a wide range of health conditions and treatments, it provides a simple descriptive profile and a single index value for health status that can be used in the clinical and economic evaluation of health care as well as in population health surveys.

Glossary of EQ-5D Terms

EQ-5D-3L	Descriptive system of health-related quality of life states consisting of five dimensions (mobility, self-care, usual activities, pain/discomfort, anxiety/depression). Each dimension has three responses recording three levels of severity (no problems/some or moderate problems/extreme problems) within a particular EQ-5D dimension.
EQ-5D-5L	Descriptive system of health-related quality of life states consisting of five dimensions (mobility, self-care, usual activities, pain/discomfort, anxiety/depression). Each dimension has five responses recording five levels of severity (no problems/slight problems/moderate problems/severe problems/extreme problems) within a particular EQ-5D dimension.
EQ-5D-Y	EQ-5D-Y Youth version. Descriptive system of youth health-related quality of life states consisting of five dimensions (mobility, looking after myself, doing usual activities, having pain or discomfort, feeling worried, sad, or unhappy). Each dimension has three responses recording three levels of severity (no problems/some problems or a bit/a lot (of) problems or very) within a particular EQ-5D dimension.
EQ-5D descriptive system	Standard layout for the above five-dimensional descriptive system for recording an individual's current EQ-5D self-reported health state (often referred to as page 2 of the EQ-5D questionnaire).
EQ-5D Self-reported health state	An EQ-5D health state recorded by an individual on the EQ-5D descriptive system.

EQ VAS	Standard vertical 20-cm visual analogue scale (similar to a thermometer) for recording an individual's rating for their current health-related quality of life state (often referred to as page 3 of the EQ-5D questionnaire).
EQ VAS score	Score recorded by an individual for their current health-related quality of life state on the EQ VAS.
EQ SDQ	Standard set of questions concerning socio-demographic variables for use with the EQ-5D valuation questionnaire and a modified version for use with the EQ-5D questionnaire. These questions are optional for users.
EQ-5D self-report questionnaire	Questionnaire, of standard layout, consisting of the EQ-5D descriptive system, the EQ VAS, and (if required) the modified version of the EQ SDQ.
EQ-5D valuation questionnaire	Questionnaire, of standard layout, consisting of the EQ-5D questionnaire (including full EQ SDQ) in addition to the EQ-5D VAS, and a standard set of instructions.
EQ-5D index value	Index value attached to an EQ-5D state according to a particular set of weights or value set.
EQ-5D value set	A scoring algorithm that can be used to attach a single index value to each EQ-5D state using a scale anchored at 1 = full health and 0 = dead. Value sets are derived from EQ-5D valuation surveys normally conducted on a representative sample of the general population of specific countries or regions, typically using the EQ-5D VAS rating scale or the time trade-off techniques.

Chapter 1

Introduction

Juan Cabasés and Rosalind Rabin

1.1 Purpose of This Book

During the 26 years since EQ-5D was first developed, a substantial amount of research has been carried out worldwide using the instrument. Among these studies were surveys conducted in various countries that measured the health-related quality of life of the general population. These studies have been informative in providing new data on population health characteristics, complementing the traditionally collected morbidity and mortality data.

The EuroQol Group is frequently asked to provide EQ-5D population reference data (sometimes called population norm data or simply population norms) for a specific country or international region. Such data can be used to compare profiles for patients with specific conditions with data for the average person in the general population in a similar age and/or gender group. Also the burden of disease in question can be compared to the general population's health.

In response to the increasing need for EQ-5D population reference data, the EuroQol Group established the Self-Reported Health Task Force whose objectives were as follows:

- Updating the international EQ-5D general population database archive.
- Providing easy-to-use tables with population norm data for individual countries.
- Illustrating the potential use of EQ-5D data in population health studies.
- Providing a recommended format to present and analyse EQ-5D data collected from future surveys.

J. Cabasés, Ph.D. (✉)

e-mail: jmcabases@unavarra.es

R. Rabin

EuroQol Group, London, UK

A first booklet summarised this work and presented population norms from population surveys conducted in 15 countries (Szende and Willimas 2004). The current book presents the population norms for 24 countries and some of their regions as well as results of some additional analyses of population health based on EQ-5D, including EQ-5D index norms.

The target audiences for this book are researchers using EQ-5D to collect data from patients or members of the general population and policy-makers using the collected information in health care decision-making. Readers wishing to learn more are encouraged to contact the EuroQol Group Executive Office (userinformationservice@euroqol.org).

1.2 EQ-5D

EQ-5D is a standardized health-related quality of life questionnaire developed by the EuroQol Group in order to provide a simple, generic measure of health for clinical and economic appraisal (EuroQol Group 1990). Applicable to a wide range of health conditions and treatments, it provides a simple descriptive profile, a self-report visual analogue scale and a single index value for health status that can be used in the clinical and economic evaluation of health care as well as in population health surveys (Fig. 1.1).

EQ-5D is designed for self-completion by respondents and is suited for use in postal surveys, web-based applications, and in face-to-face interviews. It is cognitively undemanding, taking only a few minutes to complete. The instructions to respondents are included in the questionnaire.

The EQ-5D consists of 2 pages – the EQ-5D descriptive system (page 2) and the EQ VAS (page 3). The EQ-5D descriptive system comprises five dimensions: mobility, self-care, usual activities, pain/discomfort and anxiety/depression. The EQ-5D is available in three level and five level response options, EQ-5D-3L and EQ-5D-5L, respectively, and a youth version, EQ-5D-Y.

The EQ-5D-3L (EQ-5D 3 level) was introduced in 1990 and is available in more than 160 translated versions. Although the EQ-5D-3L was initially designed for self-completion in paper-and-pencil format, EQ-5D-3L data are currently also collected electronically by web or tablet versions, or by following a telephone interviewer script. Each dimension has three levels: no problems, some problems, severe problems/unable to. The respondent is asked to indicate his/her health state by ticking (or placing a cross) in the box against the most appropriate statement in each of the five dimensions. This decision results in a 1-digit number expressing the level selected for that dimension. The digits for the five dimensions can be combined in a 5-digit number ('profile') describing the respondent's health state. It should be noted that the numerals 1–3 have no arithmetic properties and should not be used as a cardinal score.

The EQ VAS records the respondent's self-rated health on a vertical, visual analogue scale where the endpoints are labelled 'Best imaginable health state' and

By placing a tick in one box in each group below, please indicate which statements best describe your own health state today.

Mobility

- I have no problems in walking about
- I have some problems in walking about
- I am confined to bed

Self-Care

- I have no problems with self-care
- I have some problems washing or dressing myself
- I am unable to wash or dress myself

Usual Activities (*e.g. work, study, housework, family or leisure activities*)

- I have no problems with performing my usual activities
- I have some problems with performing my usual activities
- I am unable to perform my usual activities

Pain/Discomfort

- I have no pain or discomfort
- I have moderate pain or discomfort
- I have extreme pain or discomfort

Anxiety/Depression

- I am not anxious or depressed
- I am moderately anxious or depressed
- I am extremely anxious or depressed

Fig. 1.1 EQ-5D-3L

To help people say how good or bad a health state is, we have drawn a scale (rather like a thermometer) on which the best state you can imagine is marked 100 and the worst state you can imagine is marked 0.

We would like you to indicate on this scale how good or bad your own health is today, in your opinion. Please do this by drawing a line from the box below to whichever point on the scale indicates how good or bad your health state is today.

**Your own
health state**

Fig. 1.1 (continued)

‘Worst imaginable health state’. This information can be used as a quantitative measure of health outcome as judged by the individual respondents.

The responses to the EQ-5D dimensions can be used to obtain a single index value (EQ-5D index) for all health states described by the 5-digit number. Given the five dimension and three-level response option format of the EQ-5D-3L questionnaire, there are 243 possible health states plus dead and unconscious. An index value is attached to each EQ-5D state according to a particular set of weights or value sets that measure health states on a scale anchored at 1 = full health and 0 = dead. Value sets (previously also referred to as “tariffs”) were based on representative samples of the general population (as opposed to patients) of a particular country or regions, and used a technique for valuing health states with the EQ-5D VAS rating scale or the Time Trade-Off technique. A distinction should be made between the EQ-VAS self-report question for measuring health outcome and the EQ-5D valuation questionnaire that is designed to collect valuations for health states defined by the EQ-5D descriptive system using the EQ-5D VAS rating scale.

The EQ-5D index values can be used in the estimations of Quality Adjusted Life Years (QALYs) as standard QALY calculations require valuations for all relevant health states on a scale anchored at 1 = full health and 0 = dead. While the EQ-5D index values (and QALYs based on it) are often used in economic evaluation to inform priority setting in health care, the EQ-5D index values are also useful as single index measures in clinical studies as well as in population health surveys.

After extensive research and preparation, the EuroQol Group launched the EQ-5D-5L self-complete version in 2009, with the aim of further improving the sensitivity and discriminatory power of the existing EQ-5D-3L version. The EQ-5D-5L (EQ-5D 5 level) is available in more than 100 translated versions. The EQ-5D-5L still consists of two pages – the EQ-5D-5L descriptive system (page 2) and the EQ visual Analogue scale (EQ VAS) (page 3). The descriptive system comprises the same five dimensions as the EQ-5D-3L. However, each dimension now has five levels: no problems, slight problems, moderate problems, severe problems, and extreme problems/unable.

The EQ-5D-Y (EQ-5D Youth version) is an EQ-5D-3L self complete version for children and adolescents aged 7–12. It is available in more than 25 languages.

All analyses and results in this book, however, are based on adult EQ-5D-3L and EQ VAS data.

1.3 The Structure of the Book

This book presents results from four main analyses of the international EQ-5D database.

Chapter 2 presents the data sources and methods of the book. General population surveys are accumulated from 24 countries (Table 2.1). Descriptive statistics are used to provide EQ-5D population norms by age and gender categories for EQ

VAS, EQ-5D index values, and for the five dimensions. Correlations between country-specific EQ-5D data (EQ VAS and 5 dimensions) and country-specific economic and health system macro indicators are calculated in the cross-country analysis. Odds ratios and the health concentration index methodology are used in the socio-demographic analysis of EQ-5D data.

Chapter 3 presents the population norm data using EQ-5D for each country. EQ-5D norms are reported for EQ VAS and EQ-5D index values, and for self-reported problems on each of the five dimensions of the EQ-5D descriptive system, all classified by age and gender. These EQ-5D norms can be used as reference data to compare patients with specific conditions and to assess the burden of the disease in question.

Chapter 4 demonstrates that cross-country differences exist in EQ-5D outcomes after the population data is standardized for demographic differences. These cross-country differences in the general level of health are explained by looking at macro data on the economic and health system characteristics of each country. Results show that it is the prior living standards of a country that mostly explain cross-country differences in self-reported health.

Chapter 5 specifically addresses the distribution of health within the population and the degree to which age, gender, education level and country are responsible for inequalities in self-reported health. Usual activities and pain/discomfort were the highest contributors to overall inequalities in self-assessed health in most countries. Education had a consistent role in explaining a lower level of self-reported health. The level of inequalities in self-assessed health and the health inequality profile by EQ-5D dimension differed substantially across countries, deserving the attention of policy makers within each country.

Future population surveys using EQ-5D-3L or EQ-5D-5L may be integrated into the EuroQol archive of population survey datasets as they become available. Researchers planning to conduct new population surveys using EQ-5D should contact the EuroQol Group Executive Office (userinformationservice@euroqol.org).

Open Access This chapter is distributed under the terms of the Creative Commons Attribution Noncommercial License, which permits any noncommercial use, distribution, and reproduction in any medium, provided the original author(s) and source are credited.

Chapter 2

Data and Methods

Bas Janssen, Agota Szende, and Juan Manuel Ramos-Goñi

2.1 International EQ-5D Archive of Population Surveys

The international EQ-5D database archive consists of 27 EQ-5D population surveys collected in 24 countries. Countries with 1 or more population surveys include: Argentina, Armenia, Belgium, Canada, China, Denmark, England, Finland, France, Germany, Greece, Hungary, Italy, Japan, Korea, the Netherlands, New Zealand, Slovenia, Spain, Sweden, Thailand, United Kingdom, United States, and Zimbabwe. The datasets are structured in a standardized format to facilitate comparative research, although each survey also has its own characteristics and variables specific to the individual research context in which they were conducted. In addition, three datasets from Argentina, China, and Sweden (Stockholm area) were analyzed locally and results were added to the book, as the dataset transfer to the central archive was not possible from these countries. The datasets captured by this book currently include observations on 216,703 individuals. For a more detailed account of the data, see Table 2.1.

All of the surveys used a standardized version of EQ-5D-3L. The Dutch, Swedish and Finnish versions were translated in 1987 according to a ‘simultaneous’ process while the remaining versions were translated according to the EuroQol Group’s translation protocol – based on international guidelines. However, some differences between sampling and data collection methods should be noted.

Regional				
Armenia (5 regions)	Gharagebakyan 2003	2,217	2002	Face-to-face interviews on a random sample of 1300 households (2337 individuals) selected from the general population of 5 regions of Armenia (Yerevan city, Gegharkounik, Shirak, Lori, and Simnik)
Canada (Alberta)	HQCA 2010	5,010	2010	Computer Assisted Telephone Interviewing with a sample of 5010 adult Albertans
Japan (3 prefectures)	Tsuchiya et al. 2002	620	1998	Face-to-face interviews on a random sample of 972 individuals selected from the general population (over age 20) of 3 Prefectures in Japan – Saitama, Hiroshima and Hokkaido
Spain (Canary Islands)	Canary Health Survey 2009	4,468	2009	Personal computer-based home interviews on a district representative regional Canaries Health Survey to 4600 individuals
Spain (Catalonia)	Catalunya Health Survey 2011	5,603	2011	Personal computer-based home interviews on a district representative regional Catalonia Continuous Health Survey in semester waves of 2500 individuals
Sweden (Stockholm county)	Sun et al. 2012	32,597	2006	Postal survey on a representative sample of the Stockholm County population aged 20–88 years
Zimbabwe (Harare)	Jelsma 2003	2,350	2000	Face-to-face interviews with 2488 residents from Glenview (a high density suburb of Harare). As compared to the 1992 census Harare Profile, males were underrepresented and there were more young and better educated respondents than in the general population

Most importantly, while the majority of surveys were national representative surveys covering the whole of the country, some surveys covered a specific part (such as prefectures, regions or even city areas). Therefore, care should be exercised in generalizing data outside the geographic location captured by the data collection. Results in this book are reported separately for the national and the regional surveys.

Surveys also differed in sample sizes and in the method of data collection. The Argentinean dataset had the largest sample with over 41,000 respondents, while the Greek and the Swedish national surveys had the smallest sample of around 500 respondents. Some of the surveys were postal while others were performed as part of a face-to-face interview or administered by telephone. Since the questions asked in EQ-5D are very simple to answer, there is no reason to believe that there would be a significant impact on results other than differences in response rates.

While only the most recent national surveys were included in this book from each country, the date of data collection varied considerably across countries. Data collection for the majority of surveys took place during or after 2000, however some surveys were older with the United Kingdom and Swedish national datasets being the earliest from 1993 to 1994, respectively. These differences should be considered when interpreting results, given that health-related quality of life in general and specifically EQ-5D ratings and values could have changed over time.

Standardized variables across all datasets included reported problems by the five dimensions, self-reported EQ VAS ratings, and the EQ-5D index values. In addition, all analyses of EQ-5D data presented in this book focused on three main characteristics of the population: age, gender, and education level. Age in most surveys was measured as a continuous variable (life years), while gender was recorded as a categorical variable. Education level in each country was recoded to a three-level scale, distinguishing low (i.e. primary), medium (i.e. secondary), and high (i.e. university degree) education level.

All data analyses were performed using SPSS version 19 and Stata version 12 statistical software packages. All codes were checked and analyses were reproduced by a second analyst. The exact methodologies are described in the remainder of this chapter.

2.2 Methods of Describing EQ-5D Population Norms

The EuroQol Group is frequently asked to provide EQ-5D population reference data (sometimes called normative data) for a specific country or international region. Such data can be used as reference data to compare profiles for patients with specific conditions with data for the average person in the general population in a similar age and/or gender group. This comparison helps to identify the burden of disease in a particular patient population.

Descriptive statistics are provided for EQ VAS, the five dimensions, and EQ-5D-3L index values for the total population and by gender and the following age groups: 18–24, 25–34, 35–44, 45–54, 55–64, 65–74, 75+ years.

EQ-5D index value calculations are provided using the following value sets (Szendek et al. 2007):

- **European VAS value set for all countries.** Note that the European VAS value set was constructed using data from 11 valuation studies in 6 countries: Finland (1), Germany (3), The Netherlands (1), Spain (3), Sweden (1) and the UK (2). This survey included enough data from different European regions to make the European VAS dataset moderately representative for Europe. (Greiner et al. 2003; Weijnen et al. 2003).
- **Country-specific time trade-off (TTO) value set if available.** Note that the time trade-off (TTO) method has played an important role in generating value sets for the EQ-5D as one of the most widely accepted preference elicitation methods for health states (Torrance 1986) for economic evaluation and the method of choice in the first large-scale EQ-5D valuation study (Dolan 1997). Table 2.2 summarizes those 13 countries that have their own TTO value sets and describes the value sets.
- **Country-specific VAS value set if available.** Note that the Visual Analogue Scale (VAS) has become the other widely used method to elicit preferences for the EQ-5D, including nine countries. Table 2.3 summarizes countries that have their own VAS based value sets and describes the value sets, including the European value set.

This means that for countries with no available value set from their own general population, only the European VAS value set based EQ-5D index values are summarised. However, for countries with available TTO and/or VAS value sets, additional population norms of EQ-5D index values are calculated.

To summarize key results on reported problems, EQ VAS, and EQ-5D index values, countries are tabulated in alphabetic order and are not ranked. Detailed country-by-country results are provided in the appendices. Because the population norms data are presented by age and gender, there is no need for the sample to have the same age distribution as the general population in each country. Therefore the data that are presented in the tables have not been standardized for age or gender. This means that international comparisons across several age groups should be made with caution as the demographic build-up by age and gender varies between countries, and that the samples of the general population used to create the tables do not necessarily follow that same distribution. However, international comparisons of data contained in a single cell (i.e. 1 age and gender group) are valid. The following section describes the methodology used to analyse cross-country differences in EQ-5D population data.

2.3 Methods of Cross-Country Analysis of EQ-5D Data

Cross-country summary data for reported problems by five dimensions and EQ VAS were estimated using a standardized population structure for all countries with national EQ-5D surveys. Countries were tabulated in alphabetic order. Standardization for age was performed to avoid bias due to the fact that some populations have a relatively higher proportion of elderly people. Age standardization of reported problems by dimension and EQ VAS was based on the European population structure using Eurostat data from 2010 (Table 2.4).

To explore reasons for cross-country differences in EQ-5D data, correlations between country-specific EQ-5D data (EQ VAS and five dimensions) and country-specific economic and health system macro indicators were calculated.

Living standards were estimated by means of Gross Domestic Product (GDP) per capita and unemployment rate. Indicators for health care system performance were health expenditure per capita and health expenditure as a % of GDP, number of hospital beds per 1,000 people and number of physicians per 1,000 people. The indicators were selected on the basis of a presumed or possible relationship with self-reported health. Data were obtained from the World Health Organization Statistical Information System and the World Bank. The data were from 2010 or the closest year with available data (Table 2.5). An alternative set of macro data was also used to see how results might change when using macro data from the same year as the EQ-5D data collection, including variables on gross national income on purchasing power parity, unemployment rate, and health expenditure data.

For all correlation analyses, non-parametric Spearman rank correlations were calculated. For this calculation, countries were ranked based on mean self-assessed health results, and their living standards and health care system performance characteristics. A high rank correlation means that the ranking of countries on one variable (e.g. prevalence of self-reported health problems) is similar to the ranking of another variable (e.g. GDP per capita).

2.4 Methods of Sociodemographic Analysis of EQ-5D Data

Two main approaches were used to derive socio-demographic indicators based on EQ-5D, based on odds ratios and concentration indices.

Logistic regression age-adjusted odds ratios for reporting problems on each EQ-5D dimension were calculated by age groups, gender, and education. An odds ratio higher than 1 indicates that the examined group reported more health problems than the reference group. The reference group was males, 18–24 years, with medium/high education.

Secondly, the analysis used the concentration index method, which is a single index measure of relative inequalities (Wagstaff et al. 1991; Kakwani et al. 1997). The overall health concentration index measures the mean difference in health between individuals as a proportion of the average health of the total population. This index can also be interpreted as a measure of how unequal the distribution of health is in the population. Health inequality is measured on a scale between 0 (meaning complete equality in health) and 1 (meaning complete inequality in health). Researchers also showed that the concentration index value also

corresponds to 75 % of the Schutz index, and as such, it can also be interpreted as the proportion of health that should be redistributed from those above the average level to those below the average in order to equalize the distribution of health. (Koolman and Doorslaer 2004).

The overall concentration index can be decomposed to identify the impact of various factors, such as socio-demographic or quality of life characteristics, in order to determine how much each factor contributes to inequalities (Wagstaff and Doorslaer 2004; Clarke et al. 2010). In the current analysis, overall self-reported health was measured by the EQ VAS. Decomposition analysis was performed to determine inequalities by socio-demographic factors and by the EQ-5D dimensions, as well as in a combined model in which both socio-demographic and EQ-5D dimension variables were included.

The health concentration index for overall self-reported health, as measured by the EQ VAS, was computed by the convenient regression model as proposed by Kakwani et al. (1997):

$$\frac{2\sigma_R^2}{EQVAS}EQVAS_i = \alpha_i + \gamma_k R_i + \varepsilon_i$$

where R_i is the relative fractional rank of the i th individual (ranked by the individual's EQ VAS health), and γ_k is the estimated concentration index.

For the purposes of the decomposition analysis, the same estimation is used for all explanatory variables (by replacing EQ VAS with the explanatory variable in the equation and also using this variable for ranking purposes).

The total health concentration index can be written as the weighted sum of the concentration indices of the explanatory variables and the generalized concentration index of ε :

$$\hat{C} = \sum_k \hat{\eta}_k \hat{C}_{.xk} + G\hat{C}_\varepsilon$$

where the weights are equal to the elasticities of EQ VAS score with respect to each explanatory variable in the model:

$$\hat{\eta}_k = \hat{\gamma}_k \bar{x}_k / \overline{EQVAS}$$

where \bar{x}_k (the mean of x_k explanatory variables: age, gender, education, EQ-5D problems) is multiplied by the coefficients for each explanatory variable that are taken from the linear regression model to explain EQ VAS:

$$EQ - VAS = \alpha + \sum_k \gamma_k x_{ik} + \varepsilon_i.$$

Chapter 3

Population Norms for the EQ-5D

Bas Janssen and Agota Szende

3.1 Catalogue of Population Norms

Annexes 1 and 2 capture a full set of EQ-5D population norm tables that were estimated for each country. The tables contain information on the size of the study, EQ VAS ratings and proportion of reported problems on each of the EQ-5D dimensions, as well as EQ-5D index values.

Annex 1 includes surveys that were based on national representative populations. The survey for England is included among the national surveys, as it is expected to be referenced more widely in studies performed in the United Kingdom. Annex 2 includes surveys that were based on general populations but were limited to specific regions of the particular country. There are three examples where both national and regional surveys are available in a single country, including Spain, Sweden, and the United Kingdom. The choice between using the national versus the regional dataset as a reference group may well depend on the objectives and audiences of future studies. It is important to note that in all of these three countries, the regional surveys were conducted more recently. Both the survey for England and the Stockholm county survey capture a large proportion of the population in England and Sweden. The results of the English survey were similar to the UK survey, conducted 17 years previously, however no EQ VAS data were collected in the English survey. The new Stockholm county survey results show consistently worse EQ-5D population norms in all EQ-5D variables and in all age

groups. The two Spanish regional surveys also generally show worse EQ-5D population norms compared to the earlier national Spanish survey, although this is not consistently seen in all age groups.

All surveys included the EQ VAS ratings, with the exception of the Finnish and English surveys. All surveys included EQ-5D dimensions. The EQ-5D index population norms based on the European value set were calculated for all surveys. Country-specific TTO-based value sets were available for 13 countries to calculate EQ-5D index population norms. Country-specific VAS-based value sets were available for 10 countries to calculate EQ-5D index population norms. Results for sub-groups with less than 15 observations were indicated as not being available. Key results are discussed in the sections below, while all detailed tables are included in the annexes.

The population norm tables in the annexes reflect granular reporting of descriptive statistics in order to provide flexibility for researchers when using the EQ-5D norms for comparative purposes. The population norm tables can be used as reference data to compare profiles for patients with specific conditions with data for the average person in the general population in a similar age and/or gender group.

3.2 EQ VAS Population Norms

For illustration purposes, the mean EQ VAS data from all population surveys of the EuroQol archive were pooled and are presented in Fig. 3.1. As can be seen, the mean EQ VAS ratings decrease with increasing age. Also, men of all age groups reported higher EQ VAS ratings than women.

Table 3.1 shows results for self-rated EQ VAS scores for each country by age group and for the total population. It is important to note that while results in each age group may be compared across countries, the total population scores cannot be compared directly as they reflect the unique age structure within each country.

Figure 3.2 graphically presents self-rated EQ VAS scores by age group for each country. As can be seen, the mean EQ VAS ratings decrease with increasing age, although countries vary according to how younger age groups rate their health and how the slope of people's self-rated health declines over the decades of their life. Korean data show a somewhat outlier pattern in people reporting their health within a narrow EQ VAS range. This was also observed to some extent in the New Zealand data.

For easier interpretation, Figs. 3.3 and 3.4 present self-rated EQ VAS scores separately by age group for two sets of countries. The first graph shows the 'upper values' (mainly viewed from the perspective of older people), and the second the 'lower values'. Accordingly, a difference in the lower end of the Y-axis on the first figure should be noted.

Fig. 3.1 Illustration of mean population EQ VAS ratings

Table 3.1 EQ VAS ratings by age group and total population (not standardized)

	18-24	25-34	35-44	45-54	55-64	65-74	75+	Total
Argentina	82.0	79.4	77.2	74.4	69.5	67.9	62.2	75.3
Belgium	84.0	82.0	80.2	77.2	74.2	71.3	69.4	77.6

United States	86.2	83.5	81.8	79.2	76.9	75.1	68.5	80.0

Fig. 3.2 EQ VAS ratings by age group

Table 3.2 shows results for self-rated EQ VAS scores for each regional survey by age group and for the total population. As seen across the national surveys, the mean EQ VAS ratings decrease with increasing age in the regional surveys as well.

3.3 EQ-5D Dimensions

As the data on the 5 EQ-5D dimensions are not continuous but ordinal, the information is presented as the proportions of the population reporting level 1 (no problems), level 2 (some problems) and level 3 (extreme problems) per dimension, by age group and gender. Because the number of people reporting severe problems is usually very small in general population surveys, the sum of the proportions of reported level 2 and level 3 problems is sometimes used. This essentially changes the 3-level EQ-5D dimensions into 2-level dimensions, using categories ‘no problems’ and ‘problems’.

In a pooled dataset of surveys, Fig. 3.5 illustrates the sum of the proportion of reported level 2 and level 3 problems for each of the 5 EQ-5D dimensions for three distinct age groups. As can be seen from the figure, the proportion of problems increased with age on all dimensions. Problems with mobility increased the most with increasing age, whereas problems with anxiety/depression increased the least. For every age group the proportion of problems with pain/discomfort was higher than the proportion of problems on the other dimensions.

Fig. 3.3 EQ VAS ratings by age group (countries with 'upper values')

Fig. 3.4 EQ VAS ratings by age group (countries with 'lower values')

Table 3.2 EQ VAS ratings by age group and total population (not standardized) from regional surveys

	18–24	25–34	35–44	45–54	55–64	65–74	75+	Total
Armenia (5 regions)	87.8	78.4	68.0	62.3	55.3	50.1	43.8	65.7
Canada (Alberta)	81.6	80.5	78.7	75.7	77.1	77.1	75.3	78.3
Japan (3 prefectures)	78.9	77.9	79.3	79.8	76.8	76.6	67.7	77.8
Spain – Canary Islands	83.3	79.7	77.4	71.6	66.1	64.4	56.4	71.7
Spain – Catalunya	82.4	79.3	77.5	72.7	67.6	63.6	54.4	72.3
Sweden – Stockholm county	81.7	81.5	80.7	79.2	78.1	75.9	68.5	78.7
Zimbabwe – Harare district	81.8	79.8	76.6	75.1	70.5	61.5	–	79.8

Fig. 3.5 EQ-5D profile of the population (% reporting any problem)

Table 3.3 summarizes results for reported problems along the five dimensions by country. These results reflect the total population scores and cannot be compared directly to each other as they reflect the unique age structure within each country.

Table 3.3 Reported problems by 5 dimensions (% of any problem)

	Mobility	Self-care	Usual activities	Pain/discomfort	Anxiety/depression
Argentina	10.8	2.9	8.0	30.9	22.8
Belgium	12.6	4.0	12.4	28.5	6.6
China	5.1	2.8	5.2	10.7	8.7
Denmark	10.7	2.5	17.9	36.7	16.1
England	19.4	5.6	17.0	35.3	19.3
Finland	26.3	8.6	21.0	47.8	13.9
France	13.4	4.0	10.0	35.9	15.0
Germany	15.9	2.7	9.9	27.6	4.3
Greece	13.3	5.7	10.5	16.8	10.7
Hungary	19.6	6.5	14.8	39.2	35.2
Italy	10.4	3.3	9.4	26.6	8.7
Korea	5.9	0.8	4.1	21.3	17.4
Netherlands	11.5	3.4	13.5	34.2	3.5
New Zealand	20.0	4.4	21.5	40.8	21.2
Slovenia	29.8	14.0	32.9	47.2	36.4
Spain	13.7	4.1	11.7	22.9	7.8
Sweden	8.6	1.5	7.9	40.8	26.0
Thailand	26.3	8.7	22.7	65.0	47.4
United Kingdom	18.4	4.3	16.3	33.0	21.0
United States	18.5	3.7	17.9	48.3	23.2

Fig. 3.6 EQ-5D profile by country

Figure 3.6 graphically presents reported problems by dimension for each country. As can be seen, problems with pain/discomfort were generally the most prevalent, while problems with self-care were the least prevalent among the 5 dimensions.

Fig. 3.7 Reported problems with mobility (% of any problem)

Fig. 3.8 Reported problems with self-care (% of any problem)

Figures 3.7, 3.8, 3.9, 3.10 and 3.11 show reported problems for each dimension separately across all countries. Variability in reported problems for each dimension is also present among countries, with percentages of reported problem ranges of 5.1–29.8 % for mobility; 0.8–14.0 % for self-care; 4.1–32.9 % for usual activities; 10.7–65.0 % for pain/discomfort; and 3.5–47.4 % for anxiety/depression.

Table 3.4 summarizes the results for reported problems across the 5 dimensions by regional surveys. These results reflect the total population scores and cannot be compared directly to each other as they reflect the unique age structure within each country.

Fig. 3.9 Reported problems with usual activities (% of any problem)

Fig. 3.10 Reported problems with pain/discomfort (% of any problem)

3.4 EQ-5D Index Population Norms

Tables 3.5, 3.6, and 3.7 summarize key EQ-5D index value population norms by age group for each country, based on different value sets. Table 3.5 shows EQ-5D index values that are based on the European VAS value set scoring algorithm. Table 3.6 shows the available EQ-5D index values that are based on country-specific TTO value sets. Table 3.7 shows the available EQ-5D index values that are based on country-specific VAS value sets.

Fig. 3.11 Reported problems with anxiety/depression (% of any problem)

Table 3.4 Reported problems by five dimensions (% of any problem) – regional surveys

	Mobility	Self-care	Usual activities	Pain/discomfort	Anxiety/depression
Armenia (5 regions)	27.4	14.3	30.2	65.1	53.5
Canada (Alberta)	18.5	3.7	17.9	48.3	23.2
Japan (3 prefecture)	7.3	1.8	5.2	20.0	8.5
Spain-Canary Islands	17.1	6.3	14.7	39.5	25.7
Spain – Catalunya	16.9	7.0	12.4	32.9	19.5
Sweden – Stockholm county	11.6	2.1	10.4	45.2	32.7
Zimbabwe – Harare district	9.8	3.4	11.0	30.5	30.7

Therefore, cross-country differences seen in Tables 3.6 and 3.7 can be due to a mixture of differences in how people in each country report problems along the five dimensions and how different populations value these problems. Total population scores also cannot be compared for the reason that they are not standardized for demographic differences across countries. Regional data are presented using the available national TTO and VAS value sets.

Chapter 4

Cross-Country Analysis of EQ-5D Data

Agota Szende and Bas Janssen

4.1 Cross Country Comparison of Standardized EQ-5D Data

EQ VAS ratings and the rate of self-reported problems on the five dimensions within specific age groups were seen to be variable between countries in Chap. 3. However, when aggregate measures of self-assessed health are compared between countries, it is necessary to adjust for potential differences in demographics. As gender was shown to play a small role in explaining EQ-5D data, the standardization took into account age differences across countries.

Table 4.1 presents mean EQ-5D data for 18 countries with national representative population surveys where demographic characteristics were standardized based on a European population structure. Note that the data presented in Table 4.1 do not represent the actual situation in each country, but are based on the European age distribution. Because the age structure superimposed on the dataset was the same for each country, comparisons between countries can be made. When comparing Table 4.1 with the non-standardized EQ VAS ratings (Table 3.1, column for total) and 5D reported problems (Table 3.3), the results show the impact of age standardization of population norms, that are usually within a few percentage score difference.

As can be seen in Table 4.1, the data show that important differences exist in EQ-5D population data across countries after taking into account differences in population structure. Mean EQ VAS score varied from 70.37 to 83.28 in the total

France	76.32	0.144	0.046	0.107	0.358	0.145
Germany	77.16	0.172	0.031	0.105	0.278	0.045
Greece	76.50	0.172	0.083	0.137	0.204	0.112
Hungary	70.37	0.209	0.072	0.158	0.404	0.362
Italy	76.95	0.123	0.044	0.111	0.277	0.092
Korea	71.31	0.065	0.010	0.046	0.296	0.229
Netherlands	81.44	0.118	0.035	0.125	0.326	0.032
New Zealand	80.76	0.192	0.043	0.208	0.393	0.212
Slovenia	74.47	0.347	0.167	0.365	0.510	0.380
Spain	74.29	0.127	0.040	0.110	0.213	0.073
Sweden	82.49	0.113	0.025	0.096	0.425	0.264
Thailand	78.90	0.298	0.092	0.259	0.652	0.470
United Kingdom	82.75	0.182	0.043	0.162	0.331	0.209
US	79.33	0.193	0.037	0.183	0.480	0.224

population. The largest difference between any two countries in reporting problems were 28.6, 12.7, 31.9, 53.7, and 43.8 % in absolute terms along the five dimensions, respectively.

Hungary reported the lowest EQ VAS ratings, followed by Korea, while Denmark and the United Kingdom reported the highest EQ VAS ratings. The highest proportion of problems on the 5 EQ-5D dimensions was reported by Slovenia and Thailand. Note that while Hungary and Korea reported a lower mean EQ VAS than Slovenia and Thailand, more problems were reported in Slovenia and Thailand across the 5 EQ-5D dimensions. At the other end of the spectrum, China reported the lowest proportion of problems but reported average EQ VAS ratings, while Denmark and the UK reported the highest EQ VAS ratings and average proportions of problems. These results indicate that countries also differed in how they answered the more general EQ VAS question relative to how they answered the more specific questions on the EQ-5D dimensions.

4.2 The Impact of Economic and Health Care Indicators

After seeing that differences in EQ-5D data across countries exist after standardization for population structure, this section examines whether these patterns can be explained by differences in living standards and health care system

Table 4.2 Spearman rank correlations between indicators of living standards and self-reported health

EQ-VAS	GDP per capita			Health expenditure (% of GDP)			Physicians per 1,000 people		
	Age group	Unemployment rate	Health expenditure	Unemployment rate	Health expenditure	Health expenditure	per capita	per capita	people

Fig. 4.1 Self-reported EQ VAS according to GDP* per capita in 18 countries *GDP is the total value of all goods and services produced by an economy in 1 year

performance. In addition, we explored whether macro-economic variables are correlated with EQ VAS ratings and the prevalence of problems in different age groups across countries.

Table 4.2 gives an overview of Spearman rank correlation coefficients between EQ VAS ratings and self-reported health problems on EQ-5D dimensions, and indicators of living standards and health care system performance in the 18 countries. Correlations are presented for different age groups and for all age groups combined.

The prior living standards (GDP per capita) in the countries studied correlated most with the EQ VAS scores (0.58), while unemployment appeared to significantly correlate in people over the age of 45 only. Health care expenditure also correlated with better EQ VAS data (0.55). Less significant results were detected between macro indicators and reported problems.

The positive relationship between living standards and self-reported EQ VAS was further examined and is graphically presented in Fig. 4.1.

As Fig. 4.1 shows, EQ VAS correlated well with a country’s GDP, although China and Thailand were outliers with relatively high EQ VAS scores compared to their GDP.

Further linear regression analyses showed that GDP level explained 29 % of EQ VAS at the country level ($p = 0.02$), but explained 67 % of the EQ VAS when excluding ‘outliers’ China and Thailand. Health expenditure per capita was the only

other statistically significant explanatory factor that explained 26 % of the country mean VAS ($p = 0.03$). While GPD showed a stronger correlation with VAS than health expenditure, a dollar unit of health expenditure had eight times the impact of a dollar unit of GPD on the country mean VAS scores (with coefficients of 0.0001 for GPD and 0.0008 for health expenditure). Another set of regression analyses, that used macro data from the year of EQ-5D data collection in each country on gross national income expressed in purchasing power parity in 2010 values, did not reach statistically significant results. However, health care expenditure remained a statistically significant factor ($p = 0.03$), explaining 27 % of variation in the country mean VAS scores.

Chapter 5

Socio-demographic Indicators Based on EQ-5D

Agota Szende and Bas Janssen

5.1 The Use of EQ-5D in Socio-demographic Analysis

In addition to describing population norms, the EQ-5D database archive also offered the opportunity to explore health inequalities as reported by general populations of 18 countries. We have seen that age, and gender to a lesser extent, played an important role in explaining EQ-5D data across individuals. A social indicator, education, was also available in most datasets that were analysed alongside age and gender to explain EQ-5D data.

The level of attained education is important as it represents the cultural component of an individual's socio-economic status, and is an indicator of living circumstances in the earlier part of one's life. Education level is fairly stable over the life course of an individual. Later in life it shapes one's occupation and expected income potential. Through this mechanism, its indirect link with health is stronger than its direct effect (Singh-Manoux et al. 2002).

Among the higher education groups, lower prevalence of health risk factors has been observed. Given the existing health problems, individuals with a lower level of education experience greater ill-health (Eachus et al. 1999). Higher education can directly or through its vehicle mechanisms (such as being able to afford domestic help, acquisition of home appliances, reduced workload or part-time work) enable extra coping pathways that are not available to individuals with lower levels of attained education (Simon 2002). Furthermore, observational studies among people suffering from chronic conditions revealed that, through better self-management

and compliance, better treatment results can be achieved among the better-educated (Katz 1998; Karter et al. 2000; Goldman and Smith 2002). A large body of literature has shown that education is an important determinant of health indicators (Kunst et al. 1995; Mackenbach et al. 1997; Regidor et al. 1999; Borrell et al. 1999; Dalstra et al. 2002; Blakely et al. 2002; Regidor et al. 2003; von dem Knesebeck et al. 2003; Nishi et al. 2004).

Two commonly used approaches of socio-demographic analysis of health, odds ratios and concentration indices, were applied to the EQ-5D national surveys.

5.2 Odds Ratios Based on EQ-5D

The odds ratios for age, gender, and education are presented by country and by EQ-5D dimension in Table 5.1. The reference population group was men aged 18–24 years with medium or high education level. The odds ratios presented for demographic and education categories should be interpreted as relative to this reference group.

Generally, each decade of age added substantial odds for higher reported problems along all the EQ-5D dimensions. The only exception was anxiety/depression in the Netherlands and Sweden, where the odds decreased with age. In all other countries, anxiety/depression had increased odds with age but among the five dimension this dimension had the smallest odds ratio. Gender related odds ratios generally favoured men in terms of reported problems. However, exceptions included mobility, self-care, and usual activities in some countries. Gender related odds ratios were highest for self-care in Korea (6.53), self-care in Greece (4.76), and self-care in Sweden (3.06).

In most countries, attaining at least the medium level of education translated into significantly lower age- and gender-adjusted odds of experiencing problems on any dimension. Education had generally the highest impact in Korea and Slovenia, and had a particularly high impact on self-care in Sweden, with an odds ratio of 11.63.

5.3 Concentration Indices Based on EQ-5D

Results of the concentration index analysis of the 17 countries are shown in Tables 5.2, 5.3 and 5.4. Findings suggest that the level of inequalities in self-assessed EQ VAS health and the health inequality profile by EQ-5D dimension differed across countries. In terms of the overall level of inequalities, Korea, Denmark, and China presented the lowest level of relative inequalities (0.090, 0.094, and 0.095 respectively) while Spain and Hungary had the highest relative inequalities (0.173 and 0.157, respectively).

Differences were discerned in the extent to which the socio-demographic and the quality of life factors explained overall inequalities in self-assessed health.

^aEducation variable not available

Socio-demographic factors explained the smallest proportion of health inequalities in New Zealand (2.4 %), Korea (3.0 %), and Sweden (4.0 %), while they explained higher proportions in Slovenia (27.6 %) and Hungary (24.4 %).

The five dimensions of EQ-5D were generally more powerful in explaining overall self-assessed health. The explained proportion of the index varied from 14.6 % in Thailand to 54.3 % in Slovenia and Greece.

Within the socio-demographic variables, gender played the smallest role in explaining overall inequalities in self-assessed health (0–21.7 %), while age was generally the most important determinant (0–97.8 %). Education played a variable role in explaining inequalities in each country, from 0.3 % in Belgium to 93.9 % in Korea.

The health inequality profile according to the EQ-5D dimensions showed different patterns across countries. Pain/discomfort and usual activities were the highest contributors to overall inequalities in self-assessed health in most countries ($n = 8$ and $n = 7$, respectively). In Greece and Germany, mobility was the most important factor among the five dimensions. The relative share of mobility was the highest in Greece (37.5 %), while New Zealand had the highest relative share of self-care (21.7 %). Problems with usual activities contributed with the highest relative share in The Netherlands (48.0 %). Pain/discomfort had a particularly high relative share in Thailand (57.2 %) and Korea (49.6 %). The relative share of anxiety/depression was highest in China (36.4 %) in explaining overall inequalities in self-assessed health.

The decomposition analysis that combined both the socio-demographic variables and reported problems along the five dimensions confirmed the above findings. However, in this analysis, problems with usual activities became the strongest contributor to overall inequalities in the majority of countries (n=9) followed by pain/discomfort.

5.4 Conclusions

Evidence from these analyses shows that inequalities in self-reported health measured by the EQ-5D exist across many countries despite different demographic, economic and cultural characteristics. The individual health inequality profile of each country deserves the attention of policy makers to promote greater equity.

Both the analysis of odds ratios and concentration indices showed that age is the most important overall predictor of experiencing lower EQ VAS and problems on mobility, self-care, usual activities, and pain/discomfort in all countries. Gender does play an additional role, although its role is much smaller. Having attained at least a medium level of education, adjusted for age and gender, translated into lower odds of reporting problems on any dimension of EQ-5D in almost all surveyed countries. However, this relationship seemed to possess some country-specific traits that deserve the attention of policy makers.

In addition, the decomposition analysis of the concentration index provided a unique insight into the role of each individual EQ-5D dimension in explaining overall inequalities in EQ VAS. This analysis, in particular, highlighted the widespread importance of problems with pain/discomfort and usual activities in explaining inequalities in overall self-assessed health.

Finally, it has to be noted that the above results should not be used for ranking countries based on health inequality among their populations. Neither was the analysis designed to account for potential differences in demographic or other sample characteristics across countries. Each country should consider the results within the light of their own social and health care context. Further data collection and research by population subgroups that were not included in this study – such as social, ethnic, or patient groups – could help prioritize and further refine inequality reduction programs.

Another limitation of this study derives from the simple, generic nature of the EQ-5D questionnaire. The domains described by the EQ-5D-3L are generic and response options are limited to three levels. While these characteristics make the EQ-5D feasible to administer in large population surveys, they also lead to some limitations in interpreting results. For example, it is not possible to determine what proportion of reported pain related to acute, sub-acute, or chronic pain, or what were the key types of usual activities people had problem with. Targeted research along each important quality of life domain could further help understand in-depth characteristics of inequalities and identify strategies to tackle them efficiently.
